1. (45 points) For the following short answer questions, circle ALL correct answers
   For a process that can be carried out by either a reversible or an irreversible path, the change
   in \( \{P, T, V, q, E, H, w\} \) must be the same for both paths.
   \( P, T, V, E, H \)
   \( \Delta H, \Delta S, \Delta G, \Delta E \) implies constant pressure.
   \( \Delta H, \Delta G \)
   A reversible process is one that proceeds by a succession of very small incremental steps, all
   of which are (at equilibrium, spontaneous, enthalpically and entropically driven).
   At equilibrium
   The heat needed to change the phase of a substance is typically (smaller / larger) than the
   heat needed to increase its temperature by 10 K.
   Larger
   \( \Delta H \) equals the heat transferred to the system under constant \( (T, P, V) \).
   Pressure
   The path which produces the maximum work is (reversible / irreversible).
   reversible
   An ideal gas expands isothermally against an external pressure of 2 atm. \( \Delta E \) for the system is
   (greater than zero / equal to zero / less than zero).
   Zero
   An ideal gas expands adiabatically against an external pressure of 2 atm. \( \Delta E \) for the system is
   (greater than zero / equal to zero / less than zero).
   Less than zero
   An ideal gas expands adiabatically into a vacuum. \( \Delta E \) for the system is (greater than zero / equal to zero / less than zero).
   Zero
   According to the 2nd law of thermodynamics, a spontaneous process, such as a balloon filled
   with a hot gas cooling to the surroundings at constant pressure, will always occur
   (adiabatically, reversibly, irreversibly, without work done).
   Irreversibly
   The internal energy of an ideal gas is a function of only (T / P / V).
   T
   For a sample of an ideal gas, the product PV remains constant as long as (T / P / V) is held
   constant.
   \( T \) \( \text{(PV=nRT)} \)
   The 2nd law of thermodynamics states that the entropy of a (closed / isolated / isothermal)
   system always increases during a (spontaneous / equilibrium / unfavorable) process.
   isolated
   When a sample of liquid is converted reversibly to its vapor at its normal boiling point,
   \( \{q, w, \Delta P, \Delta V, \Delta T, \Delta E, \Delta H, \Delta S, \Delta G\} \) is equal to zero for the system.
   \( \Delta T, \Delta G \)
2. (25 points) Two 5 liter containers initially containing, respectively, H\textsubscript{2} and Xe gas, are separated by a valve. Considering the entire assembly to be the system, for each of the system variables below, indicate whether that value will be less than zero, greater than zero, or equal to zero, for the process which accompanies opening of the valve between the containers.

a) System variable Circle correct answer | Assumptions/comments
--- | ---
\(\Delta G\) & < \\
\(\Delta H\) & = \\
\(\Delta S\) & > \\
\(\Delta E\) & = \\
q & < \\
w & <

b) Explain in 30 words or less, your answer for \(\Delta E\).

The system is the entire assembly. Since the total pressure and the total volume (of the system) do not change, \(T = \frac{PV}{nR}\) does not change. Therefore \(\Delta E\) does not change.

c) Explain in 40 words or less, your answer for \(\Delta S\), focusing on the molecular explanation – what does it mean?

Although, the pressures don’t change, in the original situation each gas was restricted to its own container. Afterwards, the gases have more places to be / ways to arrange themselves. Entropy goes up.
3a. (15 points) Calculate $\Delta H$ and $\Delta S$ when 2 moles of H$_2$O (g) is cooled irreversibly at constant P from 120°C to 100°C.

\[
\Delta H = (2 \text{ moles}) (33.76 \text{ J K}^{-1} \text{ mol}^{-1}) (373K - 393K) = -1350J = -1.35\text{ kJ}
\]

\[
dS = \frac{dq_{rev}}{T} = C \frac{dT}{T}
\]

\[
\int_{S_1}^{S_2} dS = \int_{T_1}^{T_2} C \frac{dT}{T} = C \ln \frac{T_2}{T_1}
\]

\[
S_2 - S_1 = \Delta S = nC \ln \frac{T_2}{T_1} = (2 \text{ moles}) (33.76 \text{ J K}^{-1} \text{ mol}^{-1}) \ln \frac{373K}{393K} = -3.53\text{ JK}^{-1}
\]

3b. (15 points) Calculate $q$, $w$, $\Delta E$, $T$, and the final volume for the irreversible, isothermal expansion of 1 mole of H$_2$O (g) from an initial pressure of 1 atm and an initial volume of 1 L, to a final pressure of 0.1 atm.

$\Delta E = 0$ (isothermal)

\[
n_1 = 1 \text{ mole} \quad P_1 = 1 \text{ atm} \quad V_1 = 1 \text{ L} \quad T_1 = \frac{PV_1}{n_1R} = \frac{(1\text{ atm})(1L)}{(1\text{ mole})(0.08206 \text{ L atm K}^{-1} \text{ mole}^{-1})} = 12.2K
\]

\[
n_2 = 1 \text{ mole} \quad T_2 = T_1 \quad P_2 = 0.1 \text{ atm}
\]

\[
V_2 = \frac{n_2RT_2}{P_2} = \frac{(1\text{ mole})(0.08206 \text{ L atm K}^{-1} \text{ mole}^{-1})(12.2K)}{(0.1\text{ atm})} = 10.0L
\]

\[
w = -\int_{V_1}^{V_2} PdV = -P\int_{V_1}^{V_2} dV = -P(V_2 - V_1) = -(0.1\text{ atm})(10.0L - 1.0L) = -0.90\text{ atm L}
\]

\[
w = -0.90\text{ atm L} \left( \frac{8.314 \text{ J K}^{-1} \text{ mol}^{-1}}{0.08206 \text{ L atm K}^{-1} \text{ mole}^{-1}} \right) = -91.2J
\]

\[
q = -w = 91.2J
\]
